

Plug-in system

translate5 architecture consists of a translate5 core (which itself consists of several modules and libraries) and a plug-in system.

By using the plug-in system, a developer is able to develop functionality for translate5, which has not to be coordinated with the development of the core system. This is essential for community development on a larger Open Source project.

Most new features should be developed as plug-ins.

For more information please visit the [translate5 architecture documentation](#).
