

Install translate5 and direct dependencies

This manual requires a server environment, which matches the [mandatory dependencies](#).

- [MySQL](#)
- [Hostname](#)
- [Configure translate5 apache vhost](#)
- [PHP include path in the php.ini](#)
- [Restart apache](#)
- [Download and install Translate5](#)
- [Configure sending of mails in translate5](#)
- [Install and configure direct dependencies](#)

[Configure Cronjobs / task scheduler](#)

- [Daily](#)
- [Periodical](#)

You are done

Open your browser and call <http://translate5.local> (or whatever hostname you have configured) and have fun with translate5.

- [Remove demo users from login page](#)

MySQL

Translate5 needs a own database with character set utf8mb4. Connect to mysql

```
mysql -h localhost -u root -p
```

Then create the database, for example "translate5":

```
CREATE DATABASE IF NOT EXISTS `translate5` DEFAULT CHARACTER SET utf8mb4 COLLATE utf8mb4_unicode_ci;
```

Hostname

If you are using translate5 locally, you have to specify a hostname for your local configuration.

Please add the following line to the `/etc/hosts` file, so that your browser can reach Translate5.

We assume "translate5.local" as hostname here.

Add to the file `/etc/hosts`

```
127.0.0.1      translate5.local
```

Please ensure on pasting the above line, that between "127.0.0.1" and "translate5.local" is a TAB and not multiple spaces. In the latter case it is possible, that the name resolution does not work properly!

Configure translate5 apache vhost

Create the apache vhost config file

```
sudo touch /etc/apache2/sites-available/translate5.conf
sudo chmod 660 /etc/apache2/sites-available/translate5.conf
sudo ln -s ../sites-available/translate5.conf /etc/apache2/sites-enabled/translate5.conf
```

Edit the config file and paste the following content to it

/etc/apache2/sites-available/translate5.conf

```
<VirtualHost *:80>
  DocumentRoot "/var/www/translate5/public"
  ServerAlias translate5.local
  SetEnv APPLICATION_ENV application
  php_value include_path .:/var/www/translate5/library/zend:/usr/share/php5:/usr/share/php
  <Directory "/var/www/translate5/public">
    AllowOverride All
    Options Indexes FollowSymLinks
    Order allow,deny
    Allow from all
    Require all granted
  </Directory>
</VirtualHost>
```

Save the file.

If you use an already existing virtual host, please add at least the following setting:

```
SetEnv APPLICATION_ENV application
```

PHP include path in the php.ini

Check that the PHP include path contains at least "." and the PHP system paths. So should be something like:

```
include_path .:/usr/share/php
```

Since translate5 needs no change here, just use the system default in doubt.

Please be aware, that you have to check your webserver and this apache configuration regarding security, if you expose your translate5 instance to the internet. Your security is your responsibility and can not be covered by this manual.

Restart apache

You have to restart apache to apply all changes made to configuration.

```
sudo /etc/init.d/apache2 restart
```

Download and install Translate5

First create a translate5 directory:

```
sudo mkdir /var/www/translate5
```

Download the Translate5 core package from

URL has been removed here, since this path of installation is deprecated. Please go the docker-based way.

save and unzip it directly in the above directory.

Since apache must be able to create files in the translate5 directory, the permissions have to be changed:

```
sudo chown -R www-data:www-data /var/www/translate5
```

Then run the Translate5 "installation and update" script as www-data user, follow the instructions in the script.

```
cd /var/www/translate5
sudo -u www-data bash ./install-and-update.sh
```

In the "Translate5 Installation" step the script will ask you for the database credentials.

If your database is set up as described in [configuration from scratch](#), then all default values can be used.

The script asks also for the virtual host hostname, this must be the same hostname as specified above for the /etc/hosts file. The example name "translate5.local" is also the default in the script.

Example output of install-and-update.sh

```
Checking server for updates and packages:

Translate5 Installation
=====

Please enter the MySQL database settings, the database must already exist.
Default character set must be utf8. This can be done for example with the following command:
    CREATE DATABASE IF NOT EXISTS `translate5` DEFAULT CHARACTER SET utf8 COLLATE utf8_general_ci;

Please enter the DB host (default: localhost):
Please enter the DB username (default: root):
Please enter the DB password:
Please enter the DB database (default: translate5):

Creating the database base layout...
Translate5 tables created.

DB Config successfully stored in ./application/config/installation.ini!

Please enter the hostname of the virtual host which will serve Translate5 (default: translate5.local):

Updating Translate5 database scheme
=====

DB Update OK
    New statement files: 14
    Modified statement files: 21

Translate5 installation / update done.
Please visit http://translate5.local/ to enjoy Translate5.
In case of errors on installation / update please contact please visit http://confluence.translate5.net or post
a message in translate5 user group, which is linked from http://www.translate5.net/index/usage/.
```

Configure sending of mails in translate5

translate5 does send emails to users in different cases, e.g. when asking for a new password or on change of workflow status.

By default, sending of emails is deactivated, when using the translate5 installation-and-update-script. The reason for this is, that many users do not have an active mailserver on the machine, on which they want to test-install translate5.

If you have a mailserver running, please refer to the [installation specific configuration options](#) for information on how to configure translate5 mail sending.

Install and configure direct dependencies

Install and configure all direct dependencies to get a fully functional translate5 installation:

Configure Cronjobs / task scheduler

Depending on the usage of translate5 the setup of a cronjob / task scheduler for recurring actions is needed. Therefore exists two URLs in translate5 which must be called via cron / task scheduler.

To be able to use the cron job system, the IP Address of the system which triggers the below mentioned URLs must be configured.

This is done via the config "runtimeOptions.cronIP".

Daily

The URL <http://translate5.example.org/editor/cron/daily> should be called once a day. This triggers some date specific workflow actions, like notification of overdue tasks or deleting of old unused tasks.

Periodical

The URL <http://translate5.example.org/editor/cron/periodical> should be called each 15 Minutes. Currently this some garbage collection in translate5 and the deadline reminders. If this cronjob is not configured, the clean up is triggered by each request to translate5 once in each 15 minutes. Same for deadline reminders (which means, that without a cron periodical defined in instances with low traffic it will happen, that deadline reminders are not send at all). For performance and reliability reasons the invocation via cron job should be preferred on production systems. If the periodical cron URL was called once, translate5 reconfigures itself to use always the garbage clean up via cron, the request based trigger is automatically deactivated.

Cron Job example

```
# m h dom mon dow    command
30 23 * * * wget --no-verbose --content-on-error -O - https://example.translate5.net/editor/cron/daily 2>&1 |
grep -iz "warn\|fehl\|failed\|error\|wrong"
*/15 * * * * wget --no-verbose --content-on-error -O - https://example.translate5.net/editor/cron/periodical
2>&1 | grep -iz "warn\|fehl\|failed\|error\|wrong"

# in the example the daily cron is called at 23:30 in late evening and the periodical each 15 minutes
# the result is filters for errors only, so that cron e-mails are sent only on failures
```

You are done 😊

Open your browser and call <http://translate5.local> (or whatever hostname you have configured) and have fun with translate5.

Remove demo users from login page

For convenience of demo installations the default translate5 demo users are displayed at the login page.

To remove this go to `/client-specific/views/default/scripts/login/index.phtml` and remove the HTML that displays these users (or delete the `index.phtml` file completely).
